Introduction

The word *traffic* becomes *teletraffic* in telecommunications, as communications becomes telecommunications to indicate technology use, e.g., conversation from some distance through phones or Internet. The term teletraffic covers all kinds of computer communication traffic and telecom traffic. This book includes teletraffic loss models.

1.1. Introduction

The number of connected devices will skyrocket to 30 billion by 2025, giving rise to the well known “Internet-of-Things (IoT)” [1]. With such a huge number of IoT devices, the lifetime of networks becomes a critical issue and the conventional battery based solutions may no longer be sustainable due to the high cost of battery replacement as well as environmental concerns. As a result, wireless power transfer, which enables energy harvesting from ambient radio frequency (RF) signals, is envisioned as a promising solution for pow-

ering massive IoT devices [2, 3, 4, 5]. However, due to the significant signal attenuation in wireless communication channels, the harvested RF energy at the devices is generally limited [6, 7]. Therefore, how to efficiently utilize the scarce harvested energy becomes particularly crucial for realizing sustainable and scalable IoT networks. To this end, a “harvest and then transmit” protocol is proposed in [8, 9] for wireless powered communication networks (WPCNs), where devices first harvest energy in the downlink (DL) for wireless energy transfer (WET) and then transmit information signals in the uplink (UL) for wireless information transmission (WIT). To improve the spectral efficiency (SE), this work is further extended to a full-duplex communication network in [10] where devices can harvest energy and transmit information at the same time. However, it may not be feasible to implement the full-duplex functionality in IoT devices due to the resulting high complexity, energy consumption, and cost. As a result, the most recent narrowband IoT (NB-IoT) standard requires NB-IoT devices to support only the half-duplex protocol for simplicity [1].

Meanwhile, non-orthogonal multiple access (NOMA) has been proposed to improve the SE as well as user fairness by allowing multiple users simultaneously to access the same spectrum. With successive interference cancellation (SIC) performed at the receiver, NOMA has been demonstrated superior to orthogonal multiple access (OMA) in terms of the ergodic sum rate [11]. As such, NOMA is recently pursued for UL WIT in WPCNs [12, 13], where the decoding order of the users is exploited to enhance the throughput fairness among users. However, the conclusions drawn in [11] are only applicable for the DL scenario and may not hold for UL IoT networks with energy constrained devices. Furthermore, [12] and [13] focus only on improving the system/individual user

throughput without considering the total system energy consumption. In fact, due to the rapidly rising energy costs and the tremendous carbon footprints of existing systems, energy consumption is gradually accepted as an important design criterion for future communication systems. As such, the energy consumption of different wireless networks has been extensively studied in prior works [9, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36?] for example for heterogeneous networks, relay networks, device-to-device (D2D) communications, orthogonal frequency division multiplexing access (OFDMA), multiple-input multiple-output (MIMO), massive MIMO. However, a theoretical total energy consumption comparison between NOMA and TDMA is missing and important since the efficiency of WET is generally low in practice, which is unlike the conventional wireless networks. Also, the circuit energy consumption of the users is completely ignored in [8, 12, 13]. However, the circuit power consumption is often comparable to the transmit power and thus important for short-range IoT applications, such as wearables devices. As multiple users access the same spectrum simultaneously in NOMA, the circuit energy consumption of each user increases inevitably, which may contradict a fundamental design requirement of future IoT networks, i.e., ultra low power consumption [4]. For example, in NOMA-based WPCN (N-WPCN) with a fixed total available harvested energy, if devices consume more energy for operating their circuits than in time-division multiple access (TDMA)-based WPCN (T-WPCN), then less energy will be left for signal transmission [37]. As a result, a natural question arises: Does NOMA improve the SE and/or reduce the total energy consumption of such wireless powered IoT networks in practice compared to TDMA?

Driven by the above question, we make the following contributions in this

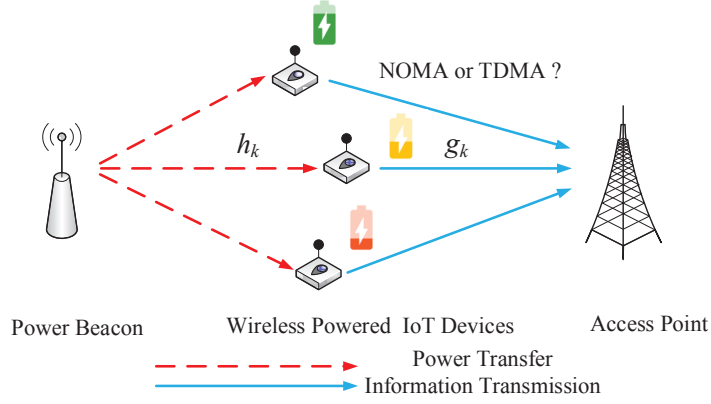

Figure 1.1: System model of a wireless powered IoT network.

paper. 1) By taking into account the circuit energy consumption, we first derive the optimal time allocation for the SE maximization problem for T-WPCN, based on which, the corresponding problem for N-WPCN can be cast as the single user case for T-WPCN; 2) we prove that N-WPCN in general requires a longer DL WET time duration than T-WPCN, which implies that N-WPCN is more energy demanding; 3) we prove that N-WPCN in general achieves a lower SE than T-WPCN. Given 2) and 3), NOMA may not be a good candidate for realizing spectral and energy efficient wireless powered IoT networks if the circuit energy consumption is not negligible.

Driven by the above question, we make the following contributions in this chapter: 1) By taking into account the circuit energy consumption, we first derive the optimal time allocation for the SE maximization problem for T-WPCN, based on which, the corresponding problem for N-WPCN can be cast as the single user case for T-WPCN; 2) we prove that N-WPCN in general requires a longer DL WET time duration than T-WPCN, which implies that N-WPCN is more energy demanding; 3) we prove that N-WPCN in general achieves a lower SE than T-WPCN. Given 2) and 3), NOMA may not be a

good candidate for realizing spectral and energy efficient wireless powered IoT networks if the circuit energy consumption is not negligible.

The remainder of this chapter is organized as follows. In Section 1.2, we describe the adopted system model and problem formulation. In Section 1.3, we analyze the performance of T-WPCN and N-WPCN. Section 1.4 presents the numerical results. Finally, we conclude the chapter in Section 1.5.

1.2. System Model and Problem Formulation

1.2.1. System Model

We consider a WPCN, which consists of one power beacon (PB), $K > 1$ wireless-powered IoT devices, and one information access point (AP), as shown in Fig. 1. The total available transmission time is denoted by T_{\max} . The “harvest and then transmit” protocol [8] is adopted where the devices first harvest energy from the signal sent by the PB and then transmit information to the AP. We note that the “doubly near-far phenomenon” [8] can be avoided by using separated PB and AP as in our model [9, 38]. For the ease of practical implementation, the power station and all users are assumed to operate in the time division manner over the same frequency band. To compare the upper bound performance of T-WPCN and N-WPCN, we assume that perfect channel state information (CSI) is available for resource allocation. The DL channel gain between the PB and device $k \in \{1, 2, \dots, K\}$, and the UL channel gain between device k and the AP are denoted by h_k and g_k , respectively.

During DL WET, the PB broadcasts the energy signal with a constant transmit power P_E for time τ_0 . The energy harvested from the noise and the received UL WIT signals from other devices are assumed to be negligible, since both the noise power and device transmit power are much smaller than the transmit power of the PB in practice [8]. Thus, the amount of harvested energy at device k can be expressed as

$$E_k^h = \eta_k P_E h_k \tau_0, \quad (1.1)$$

where $\eta_k \in (0, 1]$ is the constant energy conversion efficiency of device k . During UL WIT, device k transmits its information signal to the AP with transmit power p_k . In addition to the transmit power, each device also consumes a constant circuit power accounting for the power needed to operate its transmit filter, mixer, frequency synthesizers, etc., denoted by $p_{c,k} \geq 0$ [3, 9]. For the multiple access scheme in UL WIT, we consider two schemes, i.e., TDMA and NOMA. For T-WPCN, device k exclusively accesses the spectrum for a duration of τ_k , while for N-WPCN, all the devices access the spectrum simultaneously for a duration of $\bar{\tau}_1$. Then, the energy consumed by device k during UL WIT for T-WPCN and N-WPCN can be expressed as $(p_k + p_{c,k})\tau_k$ and $(p_k + p_{c,k})\bar{\tau}_1$, respectively. Denote $\gamma_k = \frac{g_k}{\sigma^2}$ as the normalized UL channel gain of device k , where σ^2 is the additive white Gaussian noise power at the AP. For convenience, we assume that the normalized UL channel power gains are sorted in ascending order, i.e., $0 < \gamma_1 \leq \gamma_2 \leq \dots \leq \gamma_K$.

1.2.2. T-WPCN and Problem Formulation

For T-WPCN, the achievable throughput of device k in bits/Hz can be expressed as

$$r_k = \tau_k \log_2 (1 + p_k \gamma_k). \quad (1.2)$$

Then, the system throughput of T-WPCN is given by

$$R_{\text{TDMA}} = \sum_{k=1}^K r_k = \sum_{k=1}^K \tau_k \log_2 (1 + p_k \gamma_k). \quad (1.3)$$

Accordingly, the SE maximization problem is formulated as

$$\underset{\tau_0, \{\tau_k\}, \{p_k\}}{\text{maximize}} \quad \sum_{k=1}^K \tau_k \log_2 (1 + p_k \gamma_k) \quad (1.4a)$$

$$\text{s.t.} \quad (p_k + p_{c,k}) \tau_k \leq \eta_k P_E h_k \tau_0, \quad \forall k, \quad (1.4b)$$

$$\tau_0 + \sum_{k=1}^K \tau_k \leq T_{\max}, \quad (1.4c)$$

$$\tau_0 \geq 0, \quad \tau_k \geq 0, \quad p_k \geq 0, \quad \forall k. \quad (1.4d)$$

In problem (1.4), (1.4b) is the energy causality constraint which ensures that the energy consumed for WIT does not exceed the total energy harvested during WET. (1.4c) and (1.4d) are the total time constraint and the non-negativity constraints on the optimization variables, respectively.

1.2.3. N-WPCN and Problem Formulation

For N-WPCN, since all the K devices share the same spectrum, SIC is employed at the AP to eliminate multiuser interference [11]. Specifically, for de-

tecting the message of the k -th device, the AP first decodes the message of the i -th device, $\forall i < k$, and then removes this message from the received signal, in the order of $i = 1, 2, \dots, k - 1$. The message of the i -th user, $\forall i > k$, is treated as noise. Hence, the achievable throughput of device k in bits/Hz in N-WPCN can be expressed as

$$r_k = \bar{\tau}_1 \log_2 \left(1 + \frac{p_k \gamma_k}{\sum_{i=k+1}^K p_i \gamma_i + 1} \right). \quad (1.5)$$

Then, the system throughput of T-WPCN is given by

$$R_{\text{NOMA}} = \sum_{k=1}^K r_k = \bar{\tau}_1 \log_2 \left(1 + \sum_{k=1}^K p_k \gamma_k \right). \quad (1.6)$$

Accordingly, the SE maximization problem is formulated as

$$\underset{\tau_0, \bar{\tau}_1, \{p_k\}}{\text{maximize}} \quad \bar{\tau}_1 \log_2 \left(1 + \sum_{k=1}^K p_k \gamma_k \right) \quad (1.7a)$$

$$\text{s.t.} \quad (p_k + p_{c,k}) \bar{\tau}_1 \leq \eta_k P_E h_k \tau_0, \quad \forall k, \quad (1.7b)$$

$$\tau_0 + \bar{\tau}_1 \leq T_{\max}, \quad (1.7c)$$

$$\tau_0 \geq 0, \quad \bar{\tau}_1 \geq 0, \quad p_k \geq 0, \quad \forall k. \quad (1.7d)$$

Similar to problem (1.4), (1.7b), (1.7c), and (1.7d) represent the energy causality constraint, total time constraint, and non-negativity constraints, respectively.

1.3. T-WPCN or N-WPCN?

In this section, we first derive the optimal solutions to problems (1.4) and (1.7), respectively. Then, we theoretically analyze and compare the system energy consumed and the SE achieved by both T-WPCN and N-WPCN.

1.3.1. Optimal Solution for T-WPCN

It can be shown that each device will deplete all of its energy at the optimal solution, i.e., constraint (1.4b) holds with equality, since otherwise p_k can be always increased to improve the objective value such that (1.4b) is active. Thus, problem (1.4) is simplified to the following

$$\underset{\tau_0, \{\tau_k\}}{\text{maximize}} \quad \sum_{k=1}^K \tau_k \log_2 \left(1 - p_{c,k} \gamma_k + \frac{\eta_k P_E h_k \gamma_k}{\tau_k} \tau_0 \right) \quad (1.8a)$$

$$\text{s.t.} \quad \tau_0 + \sum_{k=1}^K \tau_k \leq T_{\max}, \quad (1.8b)$$

$$\tau_0 \geq 0, \tau_k \geq 0, \forall k. \quad (1.8c)$$

It is easy to verify that problem (1.8) is a convex optimization problem and also satisfies the Slater's condition. Thus, the optimal solution can be obtained efficiently by applying the Lagrange dual method. To this end, we need the Lagrangian function of problem (1.8) which can be written as

$$\begin{aligned} \mathcal{L}(\tau_0, \{\tau_k\}) = & \sum_{k=1}^K \tau_k \log_2 \left(1 - p_{c,k} \gamma_k + \frac{\eta_k P_E h_k \gamma_k}{\tau_k} \tau_0 \right) \\ & + \lambda \left(T_{\max} - \tau_0 - \sum_{k=1}^K \tau_k \right), \end{aligned} \quad (1.9)$$

where $\lambda \geq 0$ is the Lagrange multiplier associated with (1.8b). (8c) is naturally satisfied since the PB is activated in the DL and each user is scheduled in the UL. Taking the partial derivative of \mathcal{L} with respect to τ_0 and τ_k , respectively, yields

$$\frac{\partial \mathcal{L}}{\partial \tau_0} = \sum_{k=1}^K \frac{\eta_k P_E h_k \gamma_k \log_2(e)}{1 - p_{c,k} \gamma_k + x_k} - \lambda, \quad (1.10)$$

$$\frac{\partial \mathcal{L}}{\partial \tau_k} = \log_2(1 - p_{c,k} \gamma_k + x_k) - \frac{x_k \log_2(e)}{1 - p_{c,k} \gamma_k + x_k} - \lambda, \quad (1.11)$$

where $x_k = \frac{\eta_k P_E h_k \gamma_k}{\tau_k} \tau_0, \forall k$. Since $\tau_0 > 0$ and $\tau_k > 0, \forall k$, always hold at the optimal solution, we have $\frac{\partial \mathcal{L}}{\partial \tau_0} = 0$ and $\frac{\partial \mathcal{L}}{\partial \tau_k} = 0, \forall k$. As a result, the optimal values of $x_k, \forall k$, can be obtained by solving the following set of equations

$$\begin{aligned} \mathcal{G}_k(x_k^*) &\triangleq \log_2(1 - p_{c,k} \gamma_k + x_k^*) - \frac{x_k^* \log_2(e)}{1 - p_{c,k} \gamma_k + x_k^*} \\ &\quad - \sum_{k=1}^K \frac{\eta_k P_E h_k \gamma_k \log_2(e)}{1 - p_{c,k} \gamma_k + x_k^*} = 0, \forall k. \end{aligned} \quad (1.12)$$

Note that the first two terms of $\mathcal{G}_k(x_k^*)$ monotonically increase with x_k^* while the last term is the same for all users. Thus, x_k^* can be efficiently obtained by the bisection method. It can be shown that (1.8b) is active at the optimal solution, i.e., $\tau_0 + \sum_{k=1}^K \tau_k = \tau_0 + \sum_{k=1}^K \frac{P_E h_k \eta_k \gamma_k}{x_k^*} \tau_0 = T_{\max}$. With $x_k^*, \forall k$, from (1.12), the optimal time allocation for T-WPCN is given by

$$\tau_0^* = \frac{T_{\max}}{1 + \sum_{k=1}^K \frac{\eta_k P_E h_k \gamma_k}{x_k^*}}, \quad (1.13)$$

$$\tau_k^* = \frac{\eta_k P_E h_k \gamma_k}{x_k^*} \tau_0^*, \forall k. \quad (1.14)$$

1.3.2. Optimal Solution for N-WPCN

Similarly, problem (1.7) can be simplified to the following problem:

$$\underset{\tau_0, \bar{\tau}_1}{\text{maximize}} \quad \bar{\tau}_1 \log_2 \left(1 - \sum_{k=1}^K p_{c,k} \gamma_k + \frac{\sum_{k=1}^K \eta_k P_E h_k \gamma_k}{\bar{\tau}_1} \tau_0 \right) \quad (1.15a)$$

$$\text{s.t.} \quad \tau_0 + \bar{\tau}_1 \leq T_{\max}, \quad (1.15b)$$

$$\tau_0 \geq 0, \bar{\tau}_1 \geq 0. \quad (1.15c)$$

It is interesting to observe that problem (1.15) has the same structure as problem (1.8) when $K = 1$ with only minor changes in constant terms. As such, the proposed solution for T-WPCN can be immediately extended to N-WPCN. Specifically, the optimal time allocation for N-WPCN is given by

$$\tau_0^* = \frac{T_{\max}}{1 + \frac{\sum_{k=1}^K \eta_k P_E h_k \gamma_k}{x^*}}, \bar{\tau}_1^* = \frac{\sum_{k=1}^K \eta_k P_E h_k \gamma_k}{x^*} \tau_0^*, \quad (1.16)$$

where x^* is the unique root of

$$\begin{aligned} \mathcal{G}(x^*) \triangleq & \log_2 \left(1 - \sum_{k=1}^K p_{c,k} \gamma_k + x^* \right) - \frac{x^* \log_2(e)}{1 - \sum_{k=1}^K p_{c,k} \gamma_k + x^*} \\ & - \frac{\sum_{k=1}^K \eta_k P_E h_k \gamma_k \log_2(e)}{1 - \sum_{k=1}^K p_{c,k} \gamma_k + x^*} = 0. \end{aligned} \quad (1.17)$$

The solutions proposed in Sections III-A and B serve as the theoretical foundation for the comparison between T-WPCN and N-WPCN.

1.3.3. TDMA versus NOMA

For notational simplicity, we first denote by E_{TDMA}^* and E_{NOMA}^* the total energy consumption of T-WPCN and N-WPCN at the optimal solutions to problems (1.8) and (1.15), respectively. The corresponding SEs are denoted by R_{TDMA}^* and R_{NOMA}^* , respectively.

Theorem 1.1: *At the optimal solution, 1) the DL WET time of N-WPCN in (1.16) is greater than or equal to that of T-WPCN in (1.13), i.e., $\tau_0^* \geq \tau_0^*$; 2) the energy consumption of N-WPCN is larger than or equal to that of T-WPCN, i.e.,*

$$E_{\text{NOMA}}^* \geq E_{\text{TDMA}}^*, \quad (1.18)$$

where “=” holds when $p_{c,k} = 0, \forall k$.

Proof. Since $\sum_{k=1}^K p_{c,k} \gamma_k \geq p_{c,k} \gamma_k$, it is easy to show that $x^* \geq x_k^*, \forall k$, from (1.17) and (1.12), where “=” holds when $p_{c,k} = 0, \forall k$. Then, it follows from (1.16) and (1.13) that $\tau_0^* \geq \tau_0^*$. Furthermore, since each device depletes all of its harvested energy, then the total energy consumption of N-WPCN and T-WPCN satisfies $E_{\text{NOMA}}^* = P_E \tau_0^* \geq E_{\text{TDMA}}^* = P_E \tau_0^*$.

Theorem 1.1 implies that N-WPCN is more energy demanding than T-WPCN in terms of the total energy consumption. This is fundamentally due to simultaneous transmissions of multiple devices during UL WIT, which thereby leads to a higher circuit energy consumption. Furthermore, since $\tau_0^* \geq \tau_0^*$, more energy is also wasted during DL WET for N-WPCN than for T-WPCN. Next, we compare the SE of the two networks.

Theorem 1.2: *The maximum SE of T-WPCN is greater than or equal to*

that of N -WPCN, i.e.,

$$R_{\text{TDMA}}^* \geq R_{\text{NOMA}}^*, \quad (1.19)$$

where “=” holds when $p_{c,k} = 0, \forall k$.

Proof. Assume that $\{\tau_0^*, \bar{\tau}_1^*\}$ achieves the maximum SE of problem (1.15), R_{NOMA}^* . Then, we can construct a new solution $\{\tilde{\tau}_0, \{\tilde{\tau}_k\}\}$ satisfying $\tilde{\tau}_0 = \tau_0^*$ and $\sum_{k=1}^K \tilde{\tau}_k = \bar{\tau}_1^*$ such that all devices achieve the same signal-to-noise ratio (SNR) in T-WPCN, i.e.,

$$\begin{aligned} \text{SNR} &= \frac{(\eta_k P_E h_k \tilde{\tau}_0 - p_{c,k} \tilde{\tau}_k) \gamma_k}{\tilde{\tau}_k} = \frac{(\eta_m P_E h_m \tilde{\tau}_0 - p_{c,m} \tilde{\tau}_m) \gamma_m}{\tilde{\tau}_m} \\ &= \frac{\sum_{k=1}^K (\eta_k P_E h_k \tilde{\tau}_0 - p_{c,k} \tilde{\tau}_k) \gamma_k}{\sum_{k=1}^K \tilde{\tau}_k}, \forall m \neq k. \end{aligned} \quad (1.20)$$

It can be verified that the constructed solution always exists and is also feasible for problem (1.8). Denote the SEs achieved by the optimal solution $\{\tau_0^*, \{\tau_k^*\}\}$ and the constructed solution $\{\tilde{\tau}_0, \{\tilde{\tau}_k\}\}$ as R_{TDMA}^* and \tilde{R}_{TDMA} , respectively. Then, it follows that

$$\begin{aligned} R_{\text{TDMA}}^* &\geq \tilde{R}_{\text{TDMA}} \\ &= \sum_{k=1}^K \tilde{\tau}_k \log_2 \left(1 + \frac{(\eta_k P_E h_k \tilde{\tau}_0 - p_{c,k} \tilde{\tau}_k) \gamma_k}{\tilde{\tau}_k} \right) \\ &= \sum_{k=1}^K \tilde{\tau}_k \log_2 \left(1 + \frac{\sum_{m=1}^K (\eta_m P_E h_m \tilde{\tau}_0 - p_{c,m} \tilde{\tau}_m) \gamma_m}{\sum_{m=1}^K \tilde{\tau}_m} \right) \\ &\stackrel{(a)}{\geq} \bar{\tau}_1^* \log_2 \left(1 + \frac{\sum_{m=1}^K (\eta_m P_E h_m \tau_0^* - p_{c,m} \bar{\tau}_1^*) \gamma_m}{\bar{\tau}_1^*} \right) \\ &= R_{\text{NOMA}}^*, \end{aligned} \quad (1.21)$$

where inequality “(a)” holds due to $\sum_{k=1}^K \tilde{\tau}_k = \bar{\tau}_1^*$ and $0 < \tilde{\tau}_k < \bar{\tau}_1^*, \forall k$, and the equality holds when $p_{c,k} = 0, \forall k$. Thus, if $\exists k, p_{c,k} > 0$, it follows that $R_{\text{TDMA}}^* > R_{\text{NOMA}}^*$. Next, we prove that when $p_{c,k} = 0, \forall k$, the constructed solution is the optimal solution to problem (1.8), i.e., $\tau_0^* = \tilde{\tau}_0$ and $\tau_k^* = \tilde{\tau}_k$. The SE of T-WPCN is given by

$$\begin{aligned}
R_{\text{TDMA}} &= \sum_{k=1}^K \tau_k \log_2 \left(1 + \frac{\eta_k P_E h_k \gamma_k}{\tau_k} \tau_0 \right) \\
&\stackrel{(b)}{\leq} \sum_{k=1}^K \tau_k \log_2 \left(1 + \frac{\sum_{m=1}^K \eta_m P_E h_m \gamma_m}{\sum_{m=1}^K \tau_m} \tau_0 \right) \\
&= (1 - \tau_0) \log_2 \left(1 + \frac{\sum_{m=1}^K \eta_m P_E h_m \gamma_m}{1 - \tau_0} \tau_0 \right) \\
&\stackrel{(c)}{\leq} (1 - \tau_0^*) \log_2 \left(1 + \frac{\sum_{m=1}^K \eta_m P_E h_m \gamma_m}{1 - \tau_0^*} \tau_0^* \right) \\
&= R_{\text{NOMA}}^*, \tag{1.22}
\end{aligned}$$

where “(b)” holds due to the concavity of the logarithm function and “=” holds when $\frac{\eta_k P_E h_k \gamma_k}{\tau_k} \tau_0 = \frac{\eta_m P_E h_m \gamma_m}{\tau_m} \tau_0, \forall k$, which is exactly the same as (1.20) for $p_{c,k} = 0, \forall k$. Thus, we have $\tau_k^* = \tilde{\tau}_k$. Equality in “(c)” is due to the optimality of $\bar{\tau}_0^*$ for N-WPCN. Thus, it follows that $\tau_0^* = \bar{\tau}_0^* = \tilde{\tau}_0$.

Theorem 1.2 answers the question raised in the introduction regarding to the SE comparison of T-WPCN and N-WPCN. Specifically, TDMA in general achieves a higher SE than NOMA for wireless powered IoT devices. This seems contradictory to the conclusions of previous works, e.g. [11], which have shown that NOMA always outperforms OMA schemes such as TDMA. Such a conclusion, however, was based on the conventional transmit power limited scenario where more transmit power is always beneficial for improving the SE by leveraging SIC. To show this, suppose that the transmit power of device k

is limited by p_k and the energy causality constraints in (1.4) are removed. By setting $\tau_0 = 0$ in (1.4c), we have

$$\begin{aligned}
R_{\text{TDMA}} &= \sum_{k=1}^K \tau_k \log_2(1 + p_k \gamma_k) \\
&\stackrel{(d)}{\leq} \sum_{k=1}^K \tau_k \log_2 \left(1 + \sum_{m=1}^K p_m \gamma_m \right) \\
&= T_{\max} \log_2 \left(1 + \sum_{k=1}^K p_k \gamma_k \right) = R_{\text{NOMA}}, \tag{1.23}
\end{aligned}$$

where strict inequality “(d)” holds if $p_k > 0, \forall k$. Accordingly, $E_{\text{TDMA}} = \sum_{k=1}^K \tau_k p_k \leq \sum_{k=1}^K T_{\max} p_k = T_{\max} \sum_{k=1}^K p_k = E_{\text{NOMA}}$. This suggests that the potential SE gain achieved by NOMA depends on the considered scenario. When each user has a maximum transmit power limitation p_k , which we refer to as transmit power limited scenario, all users would transmit at p_k for the entire duration T_{\max} . The resulting SE gain of NOMA is at the expense of a higher energy consumption as shown above. On the other hand, if the total available energy of each device is constrained, which we refer to as energy limited scenario, NOMA provides no SE gain over TDMA as shown in Theorem 1.2, which is consistent with the observations in [12, 13]. More importantly, when the circuit power consumption is taken into account for practical IoT devices, NOMA achieves a strictly lower SE than TDMA. Recall that the key principle of NOMA for enhancing the SE is to allow devices to access the same spectrum simultaneously. This, however, inevitably leads to a higher circuit energy consumption for NOMA because of the longer transmission time compared to TDMA, which is particularly detrimental to IoT devices that are energy limited in general.

1.4. Numerical Results

This section provides simulation results to demonstrate the effectiveness of the proposed solutions and validate our theoretical findings. There are 10 IoT devices randomly and uniformly distributed inside a disc with the PB in the center. The carrier frequency is 750 MHz and the bandwidth is 180 kHz as in typical NB-IoT systems [4]. The reference distance is 1 meter and the maximum service distance is 5 meters [38]. The AP is located 50 meters away from the PB. Both the DL and UL channel power gains are modeled as $10^{-3}\rho^2d^{-\alpha}$ [8], where ρ^2 is an exponentially distributed random variable (i.e., Rayleigh fading is assumed) with unit mean and d is the link distance. The path loss exponent is set as $\alpha = 2.2$. Without loss of generality, it is assumed that all IoT devices have identical parameters which are set as $\eta_k = 0.9$ and $p_{c,k} = 0.1$ mW, $\forall k$ [39]. Other important parameters are set as $\sigma^2 = -117$ dBm, $P_E = 40$ dBm, and $T_{\max} = 0.1$ s.

1.4.1. SE versus PB Transmit Power

Fig. 1.2 shows the achievable throughput and energy consumption versus the PB transmit power, respectively. For comparison, two baseline schemes adopting TDMA and NOMA respectively are considered, where $\tau_0 = \frac{T_{\max}}{2}$ is set for both of them. This corresponds to the case that only $E_k^h = \frac{\eta_k P_E h_k T_{\max}}{2}$ Joule of energy is available for device k , i.e., energy constrained IoT networks. Yet, the UL WIT is still optimized for maximizing the SE. In Fig. 1.2 (a), the throughputs of both T-WPCN and N-WPCN improve with P_E . This is intuitive since with larger P_E , the wireless powered IoT devices are able to harvest more energy during DL WET and hence achieve a higher throughput

in UL WIT. In addition, the baseline schemes suffer from a throughput loss for both TDMA and NOMA compared to the corresponding optimal scheme due to the fixed time allocation for DL WET, which implies that optimizing the DL WET duration is also important for maximizing the SE of wireless powered IoT networks. Furthermore, as suggested by Theorem 2, T-WPCN outperforms N-WPCN significantly and the performance gap between them becomes larger as P_E increase. This is because larger P_E will reduce the DL WET time and thereby leave more time for UL WIT. Since all the devices in N-WPCN are scheduled simultaneously for UL WIT, the circuit energy consumption will be significantly increased compared to that of T-WPCN, which thus leads to a larger performance gap. Fig. 1.2 (b) shows that N-WPCN is in general more energy demanding compared to T-WPCN for the optimal scheme, which verifies our theoretical finding in Theorem 1. Since $\tau_0 = \frac{T_{\max}}{2}$ is set for both baseline schemes, they have the same total energy consumption. In addition, when $P_E = 28$ dBm, the energy consumption of optimal N-WPCN is close to that of optimal T-WPCN, which implies that each device k , $\forall k$, basically harvests a similar amount of energy in the DL of T-WPCN and N-WPCN. As such, the substantial SE loss in Fig. 1.2 (a) indicates that a significant portion of the harvested energy is consumed by the circuit rather than for signal transmission, due to the simultaneous transmission feature of NOMA.

1.4.2. SE versus Device Circuit Power

Fig. 1.3 depicts the throughput and energy consumption versus the device circuit power consumption, respectively. Several observations are made as follows. First, for $p_{c,k} = 0$ in Fig. 1.3 (a) and (b), T-WPCN and N-WPCN achieve the

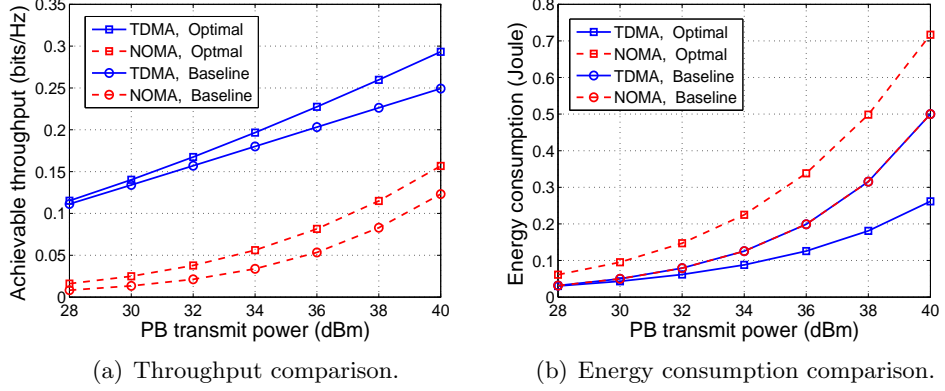

Figure 1.2: Throughput and energy consumption versus PB transmit power.

same throughput and energy consumption for $K = 10$ and $K = 50$, which coincides with our findings in Theorems 1 and 2. Second, for $K = 10$ and $K = 50$, the throughput and energy consumption for T-WPCN moderately decreases and increases with $p_{c,k}$, respectively, while that for N-WPCN decreases and increases sharply with $p_{c,k}$, respectively. This suggests that the performance of N-WPCN is sensitive to $p_{c,k}$. In fact, for T-WPCN, when a device suffers from a worse DL channel condition, the corresponding harvested energy is also less. Then, the device will be allocated a short UL WIT duration such that the energy causality constraint is satisfied. However, for N-WPCN, since all devices transmit in the UL simultaneously, to meet the energy causality of all the devices, i.e., $(p_k + p_{c,k})\bar{\tau}_1 \leq \eta_k P_E h_k \tau_0 = \eta_k P_E h_k (1 - \bar{\tau}_1)$, $\forall k$, it follows that $\bar{\tau}_1 \leq \frac{\eta_k P_E h_k}{p_k + p_{c,k} + \eta_k P_E h_k} \leq \frac{\eta_k P_E h_k}{p_{c,k} + \eta_k P_E h_k}$, $\forall k$. As can be seen, the UL WIT duration $\bar{\tau}_1$ is always limited by the worst DL channel gain of all devices for $p_{c,k} > 0$, a phenomenon which we refer to as “worst user bottleneck problem”. In addition, concurrent transmissions also lead to higher circuit energy consumption. As a result, the throughput and energy consumption of N-WPCN are significantly reduced and increased, respectively, as $p_{c,k}$ increases. Third,

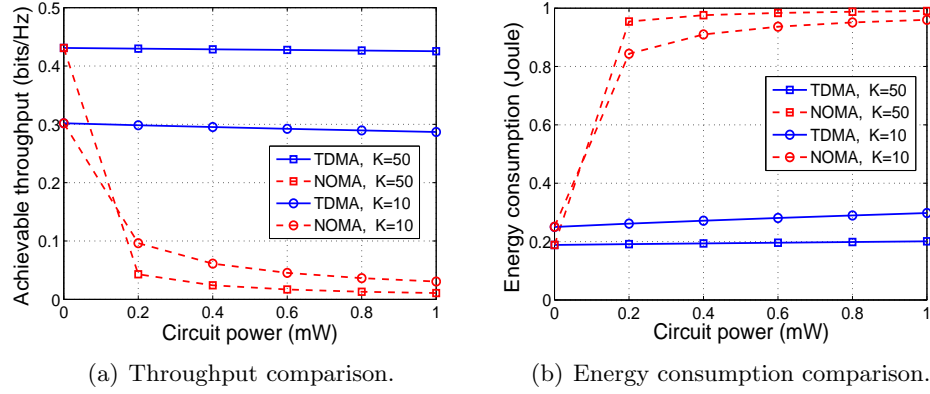

Figure 1.3: Throughput and energy consumption versus device circuit power.

given the “worst user bottleneck problem”, it is expected that when K increases from 10 to 50, the performance of N-WPCN decreases in both Fig. 1.3 (a) and (b). In contrast, for T-WPCN, since the UL WIT duration of each user can be individually allocated based on the DL and UL channel gains of each device, multiuser diversity can be exploited to improve the performances as K increases from 10 to 50.

1.5. Conclusions

In this chapter, we have answered a fundamental question: Does NOMA improve SE and/or reduce the total energy consumption of the wireless powered IoT networks? By taking into account the circuit energy consumption of the IoT devices, we have found that N-WPCN is neither spectral efficient nor energy efficient, compared to T-WPCN. This suggests that NOMA may not be a practical solution for spectral and energy efficient wireless IoT networks with energy constrained devices. The case with user fairness consideration is an interesting topic for future work.

In order to provide ubiquitous wireless energy supply to massive low-power energy-constrained devices, fixed power stations need to be deployed in an ultra-dense manner. This, however, would tremendously increase the cost, and hinder the large-scale implementation of wireless energy transfer systems. Recently, unmanned aerial vehicles (UAVs) have drawn significant research interests due to their appealing advantages such as swift and cost-effective deployment, line-of-sight (LoS) aerial-to-ground link, and controllable mobility in three-dimensional (3D) space, thus highly promising for numerous use cases in wireless communications [40, 41, 42, 43, 44, 45, 46] including ground B-S traffic offloading, mobile relaying and edge computing, information/energy broadcasting and data collection for Internet-of-Things (IoT) devices, fast network recovery after natural disasters, etc. It has been shown in [47, 48] that by exploiting the fully controllable mobility introduced by UAVs via proper trajectory design, the WPT efficiency can be significantly improved while reducing the number of required ETs as compared to the conventional WPT system with power stations deployed at fixed locations on the ground.
